THE WESTERN INDIAN OCEAN, PRESENTED TO THE NATIONAL MUSEUM BY DR. W. L. ABBOTT.

By Mary J. Rathbun,<br>Aid, Iepartment of Marine Invertebrates.

A LaRge number of erabs were recently collected by Dr. W. L. Abbott at the islands north of Madagascar. Among them are two new speeies, both of which represent rare and peenliar genera. The gemus Hypocoelus of the Cancridie ean be distinguished by the oblong or oval cavity beneath the antero-lateral border of the carapace. Three species have already been described: H. gramulatus, (De Haan), from Japan, H. diverticulatus, (Strahl) [=Cancer sculptus, Milne-Edwards, not Herbst], found sparingly from Japan to the Red Sea and Mauritius, and H. punctutus, Miers, of which a single specimen is known, from Torres Straits.

The other new form in the Abbott collection is a member of the Thel. phusan genus Deckenia, the type of which was deseribed by Hilgendorf from the adjacent African continent. This genns difters from other Thelphusidse in having the efferent branehial ehannel prolonged to the front, a character in which it approaches the Oxystomata.

## HYPOCGLUS ABBOTTI, new species.

Carapace shaped much as in H. punctatus* and strongly lobulated as in that species; but the second lobnle near the antero-lateral margin is longer than wide, and the posterior margin of the eardiac region is transverse and is distinctly separated from a small median lobule. The stirface is rongh with blunt spiniform tubercles, which also border the somewhat truncate frontal lobes and the prominent preorbital protuberances. There is a spine at the inner suborbital angle. The pterygostomian cavity is suboval, wider at its inner than its onter end. The auterior margin is straight for nearly its whole length and is formed by the antero-lateral margin of the carapace. The cavity is crossed by two ridges nearly parallel to the anterior margin, the ante-

[^0]rior ridge stopping short of the inner margin, the posterior ridge shorter and not reaching the outer margin. The surface of the abdomen and stermum is covered with bead-like tubercles except for irregular eroded chamnels or pits. The right cheliped (the left one is missing) is massive and tuberculons or spinons. The merus is short and thick, margins tuberculons, immer and outer surfaces smooth, lower surface finely tuberculons. Carpus with lower half of outer surface spiuous. Manus with upper surface subtriangular, half as broad as long; outer surface with longitudinal spinous ridges, two of which are continned on the pollex and terminate in two of the five strong teeth (one is terminal) of the prehensile edge. The dactylus bears four spinons ridges on its onter and upper surface and seven teeth on the prehensile edge which are smaller than the propodal teeth and fit closely into the spaces between them. The inmer surface of the mams is tuberenlons on its proximal lower portion. The ambulatory legs are short and broad; the last two pairs when drawn up, fit into the cavity adjoining the postero-lateral border of the rarapace. The meral joints are very broad (in the first pair the width is one-half the length), and are hollowed beneath to receive the two following joints; their anterior distal angles are produced and romded. The distal end of the propodus is much broader than the arljacent portion of the rather slender and slightly tapering dactylus.

IThfortuately it is impossible to give an accurate description of the natural color of the specimen, as with other crabs it was placed when collected in eontact with modibranch mollusks, which have given it a alark blarkish-blue color, The entire surface is: coated with a membramous covering apparently epidermie which tends to obscore the tubercles. Where this has been removed with muriatic acid the carapace appears to he blotched with bright red and white. The tips of the spines are white. The carapace is sparingly hairy, the legs are margined with hair, and the subbranchial regions are very hairy.

Measurements.-Length of carapace (of male), 55.5 mm.; wilth, 76 ; jength of manus, lower margin, 44 ; depth, 21 ; width of upuer surface, 10 ; length of merns of last ambulatory leg, upper margin, 16.5; length of carpal joint, 11 ; length of propodal joint, 6 ; length of dactylus, 10 ; width of merus, (i.5; proximal width of propodal joint, 6 ; distal width, 4 ; greatest or transverse diameter of pterggostomian davity, 25 ; opposite dimension, 11.

Locality.-Aldabra Island. (One male, No. 17753).
A. Milne-Edwarts in deseribing the genus* says that the pterygostomian cavity is concealed by the anterior feet when the latter are folded against the carapare. This is mot the case in this species. In no position does the cheliped fit tightly over the cavity. When the cheliped is folded, the upper surface of the manus is contimoms with

[^1]the inner distal portion of the onter face of the carpus. The inner border of this area corresponds in position very nearly with the posterior margin of the pterygostomian cavity; the ravity itself is therefore left meovered. The only other representative of this genus in the National Mnseum is a single specimen of $H$. Niverticulatus, from Manritius, in which the cavity is longitndinal, its margin formed by two confluent circles. When the cheliped is folded against the body, the concave upper margin of the manus and anterior carpus crosses the cavity at its middle, concealing the postrrior half, and exposing the anterior half.
H. abbotti differs from other species in the double ridge in the pterygostomian cavity, and in the carapace marked with tubercles instead of granulations, rugose lines, or puncta.

## DECKENIA CRISTATA, new species.

Carapace a little more than four-fifths as long as broad, very thick, slightly convex transversely, very convex longitudinally, antero-lateral margins strongly arcuate. There is a prominent tuberculons postfrontal crest, extending across the carapace, sinuons, intermpted at the median line and at the cervical sutme, and slightly interrupted behind the base of the eye. The median groove extends backward from the frontal margin to the postfrontal erest, where it divides into two grooves ontlining the narrow anterior portion of the mesogastrie region. The cardiacal grooves are shallow; the cervical groove is almost longitudinal for a portion of its length, then curves outward and ends at the post-frontal crest. The dorsal surface is punctate, the auterior half is covered with squamiform granules, which, on the anterior branchial regions, beeome tuberenlons and tend to form short ridges. The front is abont one-third the width of the carapace, deflexed, tuberculons, three-lobed, median lobe more advanced and much narrower than the lateral, its margin bent towards the horizontal. The margin of the front and orbit is raised, shining and indistinetly granulous. The orbital margin is sinuous, its general direction being outward and forward. The postorbital tooth is acute and more advanced than in D. imitatrix. The epibranchial tooth is smaller and not far behind the postorbital; it is followed by a row of about twenty small tuberculous tecth, forming an antero-lateral marginal line which posteriorly curves upward and inward on the carapace. The postero-lateral branchial regions are marked by transverse broken raised lines, which are coutimed on the subbranchial area. The posterior of these lines is the strongest and is contimed further inward on the dorsal surface. The suborbital margin is nearly straight, inclined in ward and slightly forward, and is finely toothed, its inner angle thickened and arljoining the end of the efferent branchial channel, which is in advance of the lateral frontal lobe and is visible from above. On the subhepatic region are two tuberenlons lines concentric to the orbit. The abdomen of the
female has the first two segments short, the third to the sixth increasing suceessively in length, the terminal segment large, subtriangular, onehalf as long as wide. Eggs very large, $3 \frac{1}{2} \mathrm{~mm}$. in diameter. The disposition of the antennal region is similar to that of $D$. imitatrix. The autennee are minnte, smaller than in that species, and smaller than the antennula. Maxillipeds similar in shape to those of 7 ). imitatrix: margin of merus and anterior margin of ischium tuberenlous.

The chelipeds are very unequal and rough with transverse sfuamose lines. The lower and inner margins of ischinm and merus are armed with triangular spines; the upper margin of the merus, with teeth which are prolongations of the rugosities of the outer surface. The carpus has a stont inner spine, with a smaller one at its base. The larger land is deep and swollen; both hands are curved inward and very rough, especially above. Digits with impressed longitudinal lines; very stout in the large cheliped; prehensile edges irregularly toothed and almost touching. The ambulatory legs are longer than in D. imitutrix. Joints margined, and with transverse rugose lines which form shallow teeth at the npper margin. Carpal and propodal joints with a donble margin above, and two more or less rough longitudinal ridges on the outer surface. Propodal joints with two rows of small appressed spines below. Dactyli flattened, longer and narrower than in 1). imitutrix, with two rows of sharp spines above and below.

Measurements.-Length of carapace (ot female), 29 mm ; width, 34 ; thickness, 18 ; wiith of front, 12 ; width between postorbital spines, 22.5 ; width between epibranchial spines, 27 ; length of propodal joint of cheliped, lower margin, 27; depth, 13.5; thickness, 8.8.

Loculity.-Seychelles. (Two females, one with egrs; one young, No. 18064).

This species differs from Deckeniu imitutrix from Zanzibar in the postfrontal crest, narrower front, rongh surface, fewer spines on the carpus, and in so many other respects that the species are not likely to be confounderl.
